This article presents two case studies of increased vibrations associated with load dispatch and removal from gas turbine-driven synchronous generators during electrical supply synchronization. The first case involves a classical uneven air gap fault due to a loose foot on the generator.

Turbine Generator Synchronization – Two Case Studies

This article presents two case studies of increased vibrations associated with load dispatch and removal from gas turbine-driven synchronous generators during electrical supply synchronization. The first case involves a classical uneven air gap fault due to a loose foot on the generator. Such faults are readily detected from the 2x line frequency associated with an electrical defect source. Another case

Synchronization is accomplished by
controlling the exciter current and the
engine speed of the generator. The need
for synchronization arrives, particularly
when two or more alternators are working
together to supply the power to the load.

Figure 2 – Generator Slower than Grid. In Figure 2 above the generator is slower than the grid. The synchroscope would be rotating rapidly counter clockwise. If the generator breaker were to be accidentally closed, the generator would be out of step with the external electrical system.

University of Gujrat has its own standby power system. In UOG for every one or two blocks there is a separate generator. These generators run on almost 30% or less load in 10 months of the year and run on almost 50% load in remaining two months May and June. In case if any of the generators beci.e. s out of order, the relevant ome

In an alternating current electric power system, synchronization is the process of matching the speed and frequency of a generator or other source to a running network. An AC generator cannot deliver power to an electrical grid unless it is running at the same frequency as the network. If two segments of a grid are disconnected, they cannot exchange AC power again until they are brought back ...

Synchronization (alternating current) - Wikipedia

The paralleling process entails connecting two or plus generators physically then synchronizing of the two generators' outputs. The conducted synchronization works by matching the waveform of one generator output voltage with the other generator's voltage waveform.

gas turbine shaft is coupled to the generator shaft, either directly or via a gearbox “direct drive” application. A gearbox is necessary in applications where the manufacturer offers the package for both 60 and 50 cycle (Hertz, Hz) applications. The gear box will use roughly 2 percent of the power developed by the turbine in these cases ...
